

Calculate greenhouse gas emissions from dairy cows

- 1 Calculate how many kilograms of carbon dioxide are stored per day in the Otway Project.
- 2 Calculate the equivalent kilograms of methane.
- 3 Decide which month you wish to use for your cow emissions (or calculate an average daily figure across the four figures given).
- 4 Calculate the number of cows that would emit the mass of methane found in **2** (don't forget to convert grams/day to kg/day).

Data

Approximate rate of carbon dioxide storage in the Otway Basin: 120 tonnes/day.

Global Warming Potential of Methane = 25 (over 100 years). To find out how much CO₂ would have the same greenhouse effect as methane, multiply the mass of methane by 25.

Methane emissions from grazing dairy cows

Month	Average methane emissions (g/cow per day)
November	487
February	623
May	521
September	344
